1.

Suppose your training examples are sentences (sequences of words). Which of the following refers to the  $j^{th}$  word in the  $i^{th}$  training example?

 $x^{(i) < j >}$ 

## Correct

We index into the  $i^{th}$  row first to get the  $i^{th}$  training example (represented by parentheses), then the  $j^{th}$  column to get the  $j^{th}$  word (represented by the brackets).

 $r^{< i>(j)}$ 

r(j) < i >

 $x^{< j > (i)}$

2.

Consider this RNN:

This specific type of architecture is appropriate when:

$$T_x = T_y$$

# Correct

It is appropriate when every input should be matched to an output.

$$T_x < T_y$$

$$T_x > T_y$$

 $igcap T_x=1$

3.

To which of these tasks would you apply a many-to-one RNN architecture? (Check all that apply).

Speech recognition (input an audio clip and output a transcript)

## **Un-selected is correct**

Sentiment classification (input a piece of text and output a 0/1 to denote positive or negative sentiment)

## Correct

Image classification (input an image and output a label)

## **Un-selected is correct**

Gender recognition from speech (input an audio clip and output a label indicating the speaker's gender)

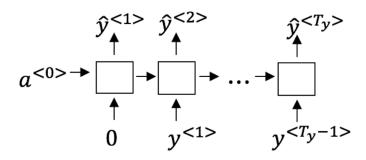

#### Correct

**/**

4.

You are training this RNN language model.

At the  $t^{th}$  time step, what is the RNN doing? Choose the best answer.

- $\qquad \qquad \text{Estimating } P(y^{<1>},y^{<2>},\dots,y^{< t-1>}) \\$
- $\bigcirc \quad \text{ Estimating } P(y^{< t>}) \\$
- $\bigcirc \quad \text{Estimating } P(y^{< t>} \mid y^{< 1>}, y^{< 2>}, \ldots, y^{< t-1>})$

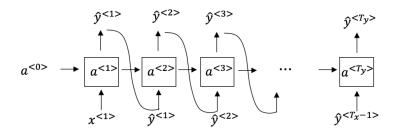

Correct

1/1 points

You have finished training a language model RNN and are using it to sample random sentences, as follows:

What are you doing at each time step t?

- (i) Use the probabilities output by the RNN to pick the highest probability word for that timestep as  $\hat{y}^{< t>}$ . (ii) Then pass the ground-truth word from the training set to the next time-step.
- (i) Use the probabilities output by the RNN to randomly sample a chosen word for that timestep as  $\hat{y}^{< t>}$ . (ii) Then pass the ground-truth word from the training set to the next time-step.
- (i) Use the probabilities output by the RNN to pick the highest probability word for that timestep as  $\hat{y}^{< t>}$ . (ii) Then pass this selected word to the next time-step.
- (i) Use the probabilities output by the RNN to randomly sample a chosen word for that timestep as  $\hat{y}^{< t>}$ . (ii) Then pass this selected word to the next time-step.

## Correct

1/1 points

You are training an RNN, and find that your weights and activations are all taking on the value of NaN ("Not a Number"). Which of these is the most likely cause of this problem? Vanishing gradient problem. Exploding gradient problem. Correct ReLU activation function g(.) used to compute g(z), where z is too large. Sigmoid activation function g(.) used to compute g(z), where z is too large. 1/1 points 7. Suppose you are training a LSTM. You have a 10000 word vocabulary, and are using an LSTM with 100-dimensional activations  $a^{< t>}$  . What is the dimension of  $\Gamma_u$  at each time step? 1 100 Correct 300

10000

8.

Here're the update equations for the GRU.

## **GRU**

$$\begin{split} \tilde{c}^{< t>} &= \tanh(W_c[\Gamma_r * c^{< t-1>}, x^{< t>}] + b_c) \\ \Gamma_u &= \sigma(W_u[c^{< t-1>}, x^{< t>}] + b_u) \\ \Gamma_r &= \sigma(W_r[c^{< t-1>}, x^{< t>}] + b_r) \\ c^{< t>} &= \Gamma_u * \tilde{c}^{< t>} + (1 - \Gamma_u) * c^{< t-1>} \\ a^{< t>} &= c^{< t>} \end{split}$$

Alice proposes to simplify the GRU by always removing the  $\Gamma_u$ . I.e., setting  $\Gamma_u$  = 1. Betty proposes to simplify the GRU by removing the  $\Gamma_r$ . I. e., setting  $\Gamma_r$  = 1 always. Which of these models is more likely to work without vanishing gradient problems even when trained on very long input sequences?

- Alice's model (removing  $\Gamma_u$ ), because if  $\Gamma_r \approx 0$  for a timestep, the gradient can propagate back through that timestep without much decay.
- Alice's model (removing  $\Gamma_u$ ), because if  $\Gamma_r \approx 1$  for a timestep, the gradient can propagate back through that timestep without much decay.
- Betty's model (removing  $\Gamma_r$ ), because if  $\Gamma_u \approx 0$  for a timestep, the gradient can propagate back through that timestep without much decay.

#### Correct

Betty's model (removing  $\Gamma_r$ ), because if  $\Gamma_u \approx 1$  for a timestep, the gradient can propagate back through that timestep without much decay.

9.

Here are the equations for the GRU and the LSTM:

 $\begin{aligned} \mathbf{GRU} & \mathbf{LSTM} \\ \tilde{c}^{< t>} &= \tanh(W_c [\Gamma_r * c^{< t-1>}, x^{< t>}] + b_c) \\ \Gamma_u &= \sigma(W_u [\ c^{< t-1>}, x^{< t>}] + b_u) \\ \Gamma_r &= \sigma(W_r [\ c^{< t-1>}, x^{< t>}] + b_r) \\ C^{< t>} &= \int_{\mathbb{R}^n} \mathbf{E}^{< t-1>} \mathbf{E}^{< t-1>$ 

From these, we can see that the Update Gate and Forget Gate in the LSTM play a role similar to \_\_\_\_\_ and \_\_\_\_ in the GRU. What should go in the the blanks?

$$\Gamma_u$$
 and  $1-\Gamma_u$ 

Correct

$$\bigcap$$
  $1-\Gamma_u$  and  $\Gamma_u$

10.

You have a pet dog whose mood is heavily dependent on the current and past few days' weather. You've collected data for the past 365 days on the weather, which you represent as a sequence as  $x^{<1>},\ldots,x^{<365>}$ . You've also collected data on your dog's mood, which you represent as  $y^{<1>},\ldots,y^{<365>}$ . You'd like to build a model to map from  $x\to y$ . Should you use a Unidirectional RNN or Bidirectional RNN for this problem?

- Bidirectional RNN, because this allows the prediction of mood on day t to take into account more information.
- Bidirectional RNN, because this allows backpropagation to compute more accurate gradients.
- Unidirectional RNN, because the value of  $y^{< t>}$  depends only on  $x^{< 1>}, \dots, x^{< t>}$  , but not on  $x^{< t+1>}, \dots, x^{< 365>}$

#### Correct

Unidirectional RNN, because the value of  $y^{< t>}$  depends only on  $x^{< t>}$ , and not other days' weather.
